## OPTIMIZATION OF FERTILE LAND USAGE AND AGRICULTURAL PRODUCTION OF TURKEY

#### Abstract

Turkey has a large amount of land which is suitable for agriculture. On the other hand, agricultural activities gradually decrease every year. Moreover, the fertile lands are not used effectively. As a result, production of agricultural goods does not satisfy the domestic demand. Thus, Turkey is obliged to import lots of agricultural goods in the recent decade.

Turkey has to develop the agricultural potential and productivity and demand supply stability as soon as possible. For this purpose, an optimization model has been developed to optimize the fertile land usage and agricultural production to satisfy the increasing agricultural demand of Turkey.

Residential settlements on fertile lands are another problem about the agricultural land usage of Turkey. The fertile lands are allowed for the construction of residential settlements and this causes the decrease of the fertile land area beside a lot of negative effects to the national economy and nature.

This study aims to find solutions to these problems with the help of an optimization model. Specifically, which parts of land has to be farmed, which products has to be cultivated, how much has to be cultivated, how much area has to be used for the cultivation of a specific product. Additionally, the model will yield the effect of loss of fertile land due to residential settlements on fertile lands.

Keywords: Agriculture, optimization, agricultural optimization, agricultural production, usage of fertile lands.

# TÜRKİYE'NİN VERİMLİ TOPRAKLARININ KULLANIMININ VE TARIMSAL ÜRETIMİNIN OPTİMİZASYONU 

## Özet

Türkiye, tarım için uygun olan büyük bir araziye sahiptir fakat tarımsal faaliyetler yıldan yıla düşüş göstermektedir. Verimli araziler etkili bir şekilde kullanılmamakta ve azalmaktadır. Bunların sonucu olarak ve nüfus artışının da etkisi ile ülkedeki üretim miktarı iç talebi karşılayamaz hale gelmiş ve pek çok ürünün ithalatı söz konusu olmuştur.

Türkiye ivedilikle, tarımsal potansiyelini, üretkenliğini ve arz-talep dengelerini geliştirip, güçlendirmelidir. Bu amaçla bir optimizasyon modeli geliştirilmiştir. Model, verimli arazilerin kullanımını ve tarımsal üretimi optimize edip, üretim miktarını arttırarak, tarımsal talebin fazlasıyla karşılanmasını sağlamaya yardımcı olmaktadır.

Imara açılan verimli tarım toprakları ve hissedilen kuraklık ise ayrı bir tarımsal üretim sorunu olarak karşımıza çıkmaktadır. Bu durum hem verimli toprak alanlarının azalmasına neden olmakta hem de ulusal ekonomiye ve doğaya ciddi zarar vermektedir.

Bu çalı̧̧ma, optimizasyon modeli ile tarımsal problemlere çözüm bulmayı amaçlamaktadır. Özellikle hangi araziler ekilecek, hangi ürün ne kadar ekilecek, belirli bir ürün için ne kadar ekim alanı kullanılacak gibi problemlere model vasıtası ile çözüm aranacaktır.

## Chapter 1

## Introduction

### 1.1 Brief History of Agriculture in Turkey

Agriculture in Turkey has been developed during from first years of the republic to nowadays. Agricultural production potential can still satisfy the domestic agricultural demand although the system has several impediments. The variety of agricultural products and their yields increase with the usage of technology. For instance; production of wheat increased $1574 \%$ and $2565 \%$ for cotton, $784 \%$ for sunflower and $8164 \%$ for potato (Dernek (2006) [1]). Similar increase rates are observed for livestock production. Moreover, with the mutual interactions, the industries which are dependent on the agriculture sector (such as food, leather, textile, machine and chemical) developed as well. The graphs of annual change in agricultural production are shown Figure (1.1).

Figure 1.1: Annual change in agricultural production (FAO [2]).

However, these agricultural developments are not enough if it is compared to European Countries. Because of unrealized land reform, imbalanced land distribution, small-scale enterprisers which have poor yield, it was not possible to use advanced technology in agricultural production.

### 1.2 General Information

Turkey has a remarkable agricultural product range. Namely; rape, banana, kiwi, avocado, fig, orange, mandarin, lemon, grapefruit, bergamot, apple, pear, quince, loquat, medlar, nectarine, peach, plum, apricot, wild apricot, cherry, morello, cranberry, oleaster, jujube, strawberry, raspberry, blackberry, berry, pomegranate, persimmon, carob, bilberry, table olive, olive, almond, nut, walnut, chestnut, pistachio, tea, chili, aniseed, cumin, raziyane, coriander, nigella, thyme, ling, indoor ornamental plants, bulb, ornamental plants, scallion, onion, garlic, dried garlic, leek, carrot, swede, red beet, celery, turnip, radish, tomato, cucumber, gherkin, pepper, okra, eggplant, zucchini, pumpkin, peas, bean, pea, fava bean, cranberry bean, melon, watermelon, pepino, caulis, broccoli, cabbage,
lettuce, artichoke, spinach, garden arch, purslane, tabooli, rocket, watercress, mint, dill, asparagus, mushroom, wheat, corn, rice plant, barley, rye, oat, millet, canary grass, triticale, sorghum, potato, broad bean, chickpea, horicot, red lentil, green lentil, vetch, greekclover, chickling, jeurselamartichoke, soya, peanut, sunflower, sesame, safflower, cole, cotton, hemp, hash, nicotina, white beet, viciasativa, clover, sainfoin seed, fodder beet, sage, lavender, melissa, stinger, rose, lupine, hop and etc. can be produced with fair yields in despite of not to use modern agricultural techniques effectively .

The graph of average yields (yields can change zone by zone) in 2014 of some products shown Figure (1.2)

Figure 1.2: Yields of some products in 2014(FAO [3]).

Turkey besides its industrialization is an agricultural country and agricultural activities are performed in all of its regions. According to different geographical and land characteristics, 12 basic agricultural zones are identified. These zones are Mediterranean, Western Anatolia, Western Black sea, Western Marmara, Eastern Black sea, Eastern Marmara, Aegean, Southeastern Anatolia, Istanbul, Northeastern Anatolia, Central Anatolia, and Middle Eastern Anatolia. These zones

Figure 1.3: Agricultural regions of Turkey. (Wikipedia).
are predefined by TURKSTAT and also they are used as a set of regions in all optimization models.

The acreage of Turkey is $814,578,000$ decares and there are 238,055,119 decares available fertile lands in 2013 according to TURKSTAT. In other words, nearly $30 \%$ of all lands are available for agricultural activities. The regional amounts of these lands shown in Figure (1.4)

Figure 1.4: Amounts of fertile lands by regional in 2013 (TURKSTAT [4]).

The percentage distribution chart of fertile lands of regions (Figure (1.5)) gives more observable picture.

Figure 1.5: Percentage distribution of fertile lands in 2013 (TURKSTAT [4]).

Since zone characteristics are different, every product cannot be planted in every zone. Moreover, their yields can change zone by zone, so product range of every zone varies out of the amount of zone's fertile lands. The regions which have a large amount of fertile lands makes it possible to plant a few crops such as; Middleeastern Anatolia and Central Anatolia. Table (1.1) contains the amounts of fertile lands, the number of highest yield products and the number of nongrowable products of each agricultural zone in 2013.

| REGION | AMOUNT <br> OF FERTILE LANDS (decares) | NUMBER <br> OF HIGH- <br> EST YIELD <br> PRODUCTS | NUMBER <br> OF NON- <br> GROWABLE <br> PRODUCTS |
| :---: | :---: | :---: | :---: |
| Mediterrenean | 23,385,270 | 31 | 13 |
| WesternAnatolia | 34,500,466 | 25 | 38 |
| WesternBlacksea | 20,506,420 | 10 | 37 |

| Istanbul | 708,986 | 15 | 61 |
| NortesternAnatolia | 12,976,835 | 3 | 64 |
| CentralAnatolia | 36,864,042 | 3 | 58 |
| MiddleesternAnatolia | 12,971,127 | 3 | 55 |

Table 1.1: Product range of regions(TURKSTAT [4]).

## Chapter 2

## Problem Definition

Turkey has a growing population (Figure (2.1)), so the consumption of agricultural products increases every year, in spite of that the efficiency of agricultural activities are not improving as it expected to be. As a result, poor production performance does not satisfy increasing consumption. Moreover, agricultural import expenditures and export revenues prove this. The following graphs (Figures (2.2) and (2.3)) represent the import and export values of all cereals and the cereal that has the biggest share in all of them namely wheat. Moreover, the most important observation on these graphs the imports had increased for last 5 years.

Figure 2.1: Population of Turkey(FAO [2]).

Figure 2.2: Annual Import and export data of total of cereals (FAO [2]).

Figure 2.3: Annual Import and export data of wheat (FAO [2]).

Additionally, despite the fact that the necessity of food increases with growing population, the amount of fertile lands decreases every year. Natural disasters are one of the reasons of this such as, erosion, flood disaster, climate changes, and depleted clean water recourses. Furthermore, there are some agricultural disasters which arise from human-related reasons. For instance, hydroelectric power plants damage fertile lands and also a natural habitat for a long run. A residential settlement on fertile lands and wrong irrigation are the other reasons. Figure (2.4) shows the significant amount of lost fertile lands:

Figure 2.4: Annual change in fertile lands (TURKSTAT [4]).

Insufficient planning of Ministry of Agriculture causes the production surplus on some products or scarcity on some other products every year. As a result, some products are not harvested; they are left on cropland, vice versa some products are imported while they can be produced. We tried to solve insufficient central organization of agricultural production problem with the help of optimization models. These models will fix some agricultural problems but not all of them. Inefficient and unavailable stocking availabilities is another cause of not harvesting the crops.

|  | 2013 Netherlands | 2013 Turkey |
| :--- | ---: | ---: |
| Total Harvested Area (ha) | $2,202,141.00$ | $54,747,488.00$ |
| Import Value (1000 US\$) | $58,500,833.00$ | $13,331,040.00$ |
| Export Value (1000 US\$) | $90,945,022.00$ | $16,556,030.00$ |
| Total Population - Both sexes (1000) | $16,809.16$ | $76,223.64$ |
| Rural population (1000) | $1,798.00$ | $20,704.00$ |
| Urban population (1000) | $14,961.12$ | $54,229.07$ |
| Cereals,Total - Yield (Hg/Ha) | $86,301.00$ | $32,567.00$ |
| Coarse Grain, Total - Yield (Hg/Ha) | $82,953.00$ | $39,837.00$ |
| Fibre Crops Primary - Yield (Hg/Ha) | $67,962.00$ | $18,463.00$ |
| Fruit excl Melons,Total - Yield <br> (Hg/Ha) | $337,267.00$ | $133,375.00$ |
| Oilcrops Primary - Yield (Hg/Ha) | $8,327.00$ | $6,324.00$ |
| Pulses,Total - Yield (Hg/Ha) | $34,411.00$ | $14,099.00$ |
| Roots and Tubers,Total - Yield <br> (Hg/Ha) | $422,075.00$ | $314,435.00$ |
| Vegetables Primary - Yield (Hg/Ha) | $571,499.00$ | $253,045.00$ |
| Vegetables\&Melons, Total - Yield <br> (Hg/Ha) | $571,499.00$ | $253,045.00$ |

Table 2.1: The agricultural comparison of Turkey and Netherlands(FAO [3]).

As is seen from Table (2.1), Turkey had had so bad agricultural profile compared to Netherlands. Turkey had harvested area nearly 25 times more than Netherlands, but agricultural export value of Netherlands had been nearly 6 times more than Turkey's agricultural export value. It is not true that this situation just depends on difference in populations of these two country. Yields of Netherlands are very higher than yields of Turkey. Of course it is not possible to solve the agricultural problems of Turkey by just comparing the parameters of these two countries. The models will just reorganize production with existing yields and other parameters and try to increase agricultural efficiency of Turkey.

## Chapter 3

## Literature Review

Agricultural production planning problem has been examined in operations research, agricultural economics and operation management literatures. For instance, Lu at al. (2013) [5] had been developed an optimization model called interval - probabilistic agricultural production structure optimization model (IPAPSOM). The IPAPSOM considers food security policies, increasing rural household's income, resource preservation, eco-environment conservation, risk of violating. Additionally, it works in multi-period planning horizon. It had been applied to a real case of long-term agricultural production structure optimization in Dancheng Country in Province of Central China. IPAPSOM contains multiple agricultural industry types and it has multiple objectives and multiple objective technologies. It has also complex, uncertain and dynamic characteristics. Even if IPAPSOM has more or less similar aims with our models but it holds different considerations and characteristics from ours'. Detailed information is given about our models in Chapter 4. The another interval - probabilistic programming study had been developed by Lu at al. (2015) [6]. It works under uncertainties like Lu at al. (2013) [5].

There is an implementation of farm planning in Model Building in Mathematical Programming (1999)[7] and it based on Swart at al. (1975)[8]. It is a multi-period model and considers to make maximum profit in five year. There are determined constant total farm lands and grain and sugar beets are grown on these farm
lands to feed dairy cows. The aims of the model are to make decisions how much lands to use growing grain and sugar beets, how much grain and sugar beets to buy or to sell and how many heifers to sell in each year. Our models works for one single year and it is the most basic difference from this model. Moreover, it works for farm land in other words for a small share of land, our models work for all country.

Ahmet at al. (2015) [9] considers to develop quantity of agricultural production in a province of Pakistan called Punjab. They had worked a multi-objective optimization model which includes agriculture, forestry, animal husbandry and fishery sectors to maximize total income. The model consists ecological and environmental and industry relation constraints as well as resource and demand constraints. Haddad at al. (2012) [10] had been studied on another agricultural production optimization for Jordan Valley which specified financial risk of water.

A study (Heady at al. (1964) [11]) which consists a linear programming had aimed to determine regional production patterns for specified farm commoditions in the United States. It had worked on 122 agricultural regions and tried to determine which field in these regions that crops be produced and to find out total acreage required to produce crops basically. Moreover an early study (Heady at al. (1959) [12]) of reginal programming in United States exists to have same basic aims with Heady at al. (1964) [11]. Furthermore, a multi-period mixed integer programming model had been created Glen (1996) [13] for development of livestock specialized deer farming in the UK.

## Chapter 4

## The Optimization Models

### 4.1 Model 1: LP Approach 1

The first model organizes cultivable lands in all regions in Turkey such that which agricultural product has to be produced, of what amount of area, in which region so that the production amounts of products would be increased and high level of domestic and export demands could be satisfied. Furthermore, the model decreases import amounts of products. Details of the model are given following parts:

### 4.1.1 Sets of model 1:

$I$ : set of products.
$J$ : set of regions be appropriate for agricultural production.

### 4.1.2 Parameters of model 1:

$p_{i}$ : Unit domestic price of product i $(\$ /$ ton $)$
$e_{i}$ : Unit export price of product $\mathrm{i}(\$ /$ ton $)$
$d_{i}$ : Domestic demand of product i for the specific year (ton)
$o_{i}$ : Export demand of product i for the specific year (ton)
$c_{i}$ : Unit cost of unsold product i (\$/ton)
$K_{j}$ : Amount of fertile land in region j (decare)
$r_{j}$ : Opportunity cost of unused fertile agricultural area in region j ( $\$ /$ decare)
cost $_{i j}$ : Unit cost of planting product i in region j ( $\$ /$ decare)
$v_{i j}$ : Productivity level of product i in region j (ton/decare)
impCost $_{i}$ : Unit cost of imported product i (\$/ton)
$o h_{i}$ : On hand inventory of product i (ton)

### 4.1.3 Decision variables of model 1 :

$x_{i}$ : Amount of production of product i for domestic consumption for the specific year (ton)
$y_{i}$ : Amount of production to export of product ifor the specific year (ton)
$k a_{i j}$ : Amount of needed area in region j to produce product i (decare)
$T_{i}$ : Total amount of production of product i for the specific year (ton)
import $_{i}$ : Amount of import of product i for the specific year (ton)
impx $i_{i}$ : Amount of imported product i which is consumed in domestic market (ton)
impy $_{i}$ : Amount of imported product i which for export (ton)
oh $x_{i}$ : Amount of on-hand inventory product i which is consumed in domestic market (ton)
ohy $y_{i}$ : Amount of on-hand inventory of product i to export (ton)

### 4.1.4 Model 1:

$$
\begin{align*}
& \max _{\text {profit }} \sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \\
& +\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \\
& -\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \\
& -\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \\
& -\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \\
& -\sum_{\forall i \in I}\left(\text { imp Cost }_{i} * \text { import }_{i}\right) \\
& \text { s.t. } \begin{aligned}
x_{i}+y_{i} & \leq T_{i} & & \forall i \in I \\
x_{i}+i m p x_{i}+o h x_{i} & =d_{i} & & \forall i \in I \\
y_{i}+i m p y_{i}+o h y_{i} & \leq o_{i} & & \forall i \in I \\
o h x_{i}+o h y_{i} & =h_{i} & & \forall i \in I \\
i m p x_{i}+i m p y_{i} & =\text { import }_{i} & & \forall i \in I \\
\sum_{\forall j \in J}\left(v_{i j}+k a_{i j}\right) & =T_{i} & & \forall i \in I \\
\sum_{\forall i \in I} k a_{i j} & \leq K_{j} & & \forall j \in J \\
x_{i}, y_{i} & \geq 0 & & \forall i \in I \\
i m p o r t_{i}, i m p x_{i}, i m p y_{i} & \geq 0 & & \forall i \in I \\
o h x_{i}, o h y_{i} & \geq 0 & & \forall i \in I \\
k a_{i j} & \geq 0 & & \forall i \in I, \forall j \in J
\end{aligned} \tag{4.1}
\end{align*}
$$

### 4.1.5 Description of model 1 :

### 4.1.5.1 Objective function of model 1:

The revenue according to domestic consumption:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \tag{4.2}
\end{equation*}
$$

The domestic market demand is satisfied by the sum of domestic production, import and on hand inventory usage for domestic consumption. The sum of the product of price and the domestic consumption gives us the revenue.

The revenue of export:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \tag{4.3}
\end{equation*}
$$

Overseas demand is satisfied likewise domestic market demand.

Unsold cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \tag{4.4}
\end{equation*}
$$

For a product, if the sum of production for domestic consumption and production for export is not equal to (lower than) total production, there are the unconsumed amount of that product. Additionally, unsold costs of products were defined as parameter according to these unconsumed products. If a product is perishable like tabooli, its unsold cost is equal production cost; otherwise, (like wheat) unsold cost is equal holding cost.

Production cost:

$$
\begin{equation*}
\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \tag{4.5}
\end{equation*}
$$

There is a unit production cost to produce a product on a region and a decision variable which is the amount of land used to produce a product. The sum product of this two gives total production cost.

Opportunity cost:

$$
\begin{equation*}
\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \tag{4.6}
\end{equation*}
$$

The unused fertile lands cause economic loss. In other words, some products can be planted on uncropped lands and earned income. So, the unit opportunity cost
was determined for each region as the average price of all appropriate products which can be planted a region. The sum product of uncropped area and unit opportunity cost gives total opportunity cost.

Import Cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(\text { imp }^{\text {ost }} i * * \text { import }_{i}\right) \tag{4.7}
\end{equation*}
$$

The sum product of unit import cost and amount of import of each products gives total import cost.

### 4.1.5.2 Constraints of model 1 :

$$
\begin{equation*}
x_{i}+y_{i} \leq T_{i} \quad \forall i \in I \tag{4.8}
\end{equation*}
$$

The sum of domestic and export sales of a product which was produced domestically must be lower than the total amount of domestic production (equation 4.8).

$$
\begin{equation*}
x_{i}+i m p x_{i}+o h x_{i}=d_{i} \quad \forall i \in I \tag{4.9}
\end{equation*}
$$

There are three ways to satisfy the domestic demand as follows, domestic production, import, and stocks. Domestic demand has to be satisfied (equation 4.9).

$$
\begin{equation*}
y_{i}+i m p y_{i}+o h y_{i} \leq o_{i} \quad \forall i \in I \tag{4.10}
\end{equation*}
$$

Likewise domestic demand, there are also three ways to satisfy the overseas demand. Note that, the imported products can be exported. Overseas demand has not to be satisfied completely (equation 4.10).

$$
\begin{equation*}
o h x_{i}+o h y_{i}=o h_{i} \quad \forall i \in I \tag{4.11}
\end{equation*}
$$

Products in inventory can be consumed in the domestic market or exported. However, they must be exactly consumed (equation 4.11).

$$
\begin{equation*}
{i m p x_{i}}^{\left.+i m p y_{i}=\text { import }_{i} \quad \forall i \in I=1\right)} \tag{4.12}
\end{equation*}
$$

Imported products can be consumed in the domestic market or exported. The amount of import a product is as needed (equation 4.12).

$$
\begin{equation*}
\sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right)=T_{i} \quad \forall i \in I \tag{4.13}
\end{equation*}
$$

Each area has a measured productivity for each product. So, the sum of product of productivity and amount of area is equal to total amount of production (equation 4.13).

$$
\begin{equation*}
\sum_{\forall i \in I} k a_{i j} \leq K_{j}=T_{i} \quad \forall j \in J \tag{4.14}
\end{equation*}
$$

The amount of fertile lands of each area was measured. The sum of used area for production can not to be higher than the amount of fertile lands (equation 4.14).

$$
\begin{equation*}
x_{i}, y_{i}, \text { ka } a_{i j}, \text { import }_{i}, i m p x_{i}, \text { impy }_{i}, \text { oh } x_{i}, \text { oh } y_{i} \geq 0 \quad \forall i \in I, \forall j \in J \tag{4.15}
\end{equation*}
$$

All variables must be positive (equation 4.15).

### 4.2 Model 2: LP Approach 2

Agricultural cultivable lands can be organized by the first model but there is an important handicap of it. The assumption of the first model was that every product can be cultivated on every part of regions according to their yields. However, the farmers have divided their lands to several portions to produce several products and it makes no sense to produce cereals on orchards at the cost of cutting fruit trees. So product groups (cereals, fruits, vegetables and ornament plants) were defined and upper limits of these were added in the model. Moreover, there are uncultivated lands (fallowed areas) in every region so these lands might be considered. Thus, the model could reflect real life better.

### 4.2.1 Sets of model 2:

$I$ : set of products.
$J$ : set of regions be appropriate for agricultural production.
$M$ : set of product groups.

### 4.2.2 Parameters of model 2:

$p_{i}$ : Unit domestic price of product i $(\$ /$ ton $)$
$e_{i}$ : Unit export price of product i (\$/ton)
$d_{i}$ : Domestic demand of product i for the specific year (ton)
$o_{i}$ : Export demand of product i for the specific year (ton)
$c_{i}$ : Unit cost of unsold product i (\$/ton)
$K_{j}$ : Amount of fertile land in region j (decare)
$r_{j}$ : Opportunity cost of unused fertile agricultural area in region j (\$/decare)
$\operatorname{cost}_{i j}$ : Unit cost of planting product i in region j ( $\$ /$ decare)
$v_{i j}$ : Productivity level of product i in region j (ton/decare)
imp $^{\text {Cost }}{ }_{i}$ : Unit cost of imported product i $(\$ /$ ton $)$
$o h_{i}$ : On hand inventory of product $\mathrm{i}(\mathrm{ton})$
$b_{m j}$ : Usable amount of area j to produce product group m

### 4.2.3 Decision variables of model 2:

$x_{i}$ : Amount of production of product i for domestic consumption for the specific year (ton)
$y_{i}$ : Amount of production to export of product i for the specific year (ton)
$k a_{i j}$ : Amount of needed area in region j to produce product i (decare)
$T_{i}$ : Total amount of production of product i for the specific year (ton)
import $_{i}$ : Amount of import of product i for the specific year (ton)
$i_{i m p x}$ : Amount of imported product i which is consumed in domestic market (ton)
impy $_{i}$ : Amount of imported product i which for export (ton)
oh $x_{i}$ : Amount of on-hand inventory product i which is consumed in domestic market (ton)
ohy $y_{i}$ : Amount of on-hand inventory of product i to export (ton)

### 4.2.4 Model 2:

$$
\begin{align*}
& \max _{\text {profit }} \sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \\
& +\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \\
& -\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \\
& -\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \\
& -\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \\
& -\sum_{\forall i \in I}\left(\text { imp Cost }_{i} * \text { import }_{i}\right) \\
& \text { s.t. } \\
& \begin{aligned}
x_{i}+y_{i} & \leq T_{i} & & \forall i \in I \\
x_{i}+i m p x_{i}+\text { oh } x_{i} & =d_{i} & & \forall i \in I \\
y_{i}+i m p y_{i}+o h y_{i} & \leq o_{i} & & \forall i \in I \\
\text { oh } x_{i}+o h y_{i} & =\text { oh }_{i} & & \forall i \in I \\
i m p x_{i}+i m p y_{i} & =\text { import }_{i} & & \forall i \in I \\
\sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right) & =T_{i} & & \forall i \in I
\end{aligned}  \tag{4.16}\\
& \sum_{\forall i \in I} k a_{i j} \leq K_{j}-b_{\text {FallowArea, },} \quad \forall j \in J \\
& \sum_{i \in m=\text { Cereals }} k a_{i j} \leq b_{\text {Cereals }, j} \quad \forall j \in J \\
& \sum_{i \in m=\text { Vegetables }} k a_{i j} \leq b_{\text {Vegetables }, j} \quad \forall j \in J \\
& \sum_{i \in m=\text { Fruits }} k a_{i j} \leq b_{\text {Fruits }, j} \quad \forall j \in J \\
& \sum_{\text {rnamentPlants }}^{i \in m=F \text { ruits }} k a_{i j} \leq b_{\text {OrnamentPlants }, j} \quad \forall j \in J \\
& x_{i}, y_{i} \geq 0 \\
& \forall i \in I \\
& \text { import }_{i}, i m p x_{i}, \text { impy }_{i} \geq 0 \quad \forall i \in I \\
& \text { oh } x_{i}, \text { ohy } y_{i} \geq 0 \quad \forall i \in I \\
& k a_{i j} \geq 0 \quad \forall i \in I, \forall j \in J
\end{align*}
$$

### 4.2.5 Description of model 2:

### 4.2.5.1 Objective function of model 2:

The revenue according to domestic consumption:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \tag{4.17}
\end{equation*}
$$

The domestic market demand is satisfied by the sum of domestic production, import and on hand inventory usage for domestic consumption. The sum of the product of price and the domestic consumption gives us the revenue.

The revenue of export:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \tag{4.18}
\end{equation*}
$$

Overseas demand is satisfied likewise domestic market demand.

Unsold cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \tag{4.19}
\end{equation*}
$$

For a product, if the sum of production for domestic consumption and production for export is not equal to (lower than) total production, there are the unconsumed amount of that product. Additionally, unsold cost of a product is defined as a parameter according to these unconsumed products. If a product is perishable like tabooli, its unsold cost is equal production cost; otherwise, (like wheat) unsold cost is equal holding cost.

Production cost:

$$
\begin{equation*}
\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \tag{4.20}
\end{equation*}
$$

There is a unit production cost to produce a product on a region and a decision variable which is the amount of land used to produce a product. The sum product of this two gives total production cost.

Opportunity cost:

$$
\begin{equation*}
\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \tag{4.21}
\end{equation*}
$$

The unused fertile lands cause economic loss. In other words, some products can be planted on uncropped lands and earned income. So, the unit opportunity cost was determined for each region as the average price of all appropriate products which can be planted a region. The sum product of uncropped area and unit opportunity cost gives total opportunity cost.

Import Cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(\text { imp Cost }_{i} * \text { import }_{i}\right) \tag{4.22}
\end{equation*}
$$

The sum product of unit import cost and amount of import of each item gives total import cost.

### 4.2.5.2 Constraints of model 2:

$$
\begin{equation*}
x_{i}+y_{i} \leq T_{i} \quad \forall i \in I \tag{4.23}
\end{equation*}
$$

The sum of domestic and export sales of a product which was produced domestically must be lower than the total amount of domestic production (equation 4.23).

$$
\begin{equation*}
x_{i}+i m p x_{i}+o h x_{i}=d_{i} \quad \forall i \in I \tag{4.24}
\end{equation*}
$$

There are three ways to satisfy the domestic demand as follows, domestic production, import, and stocks. Domestic demand has to be satisfied (equation 4.24).

$$
\begin{equation*}
y_{i}+i m p y_{i}+o h y_{i} \leq o_{i} \quad \forall i \in I \tag{4.25}
\end{equation*}
$$

Likewise domestic demand, there are also three ways to satisfy the overseas demand. Note that, the imported products can be exported. Overseas demand has not to be satisfied completely (equation 4.25).

$$
\begin{equation*}
o h x_{i}+o h y_{i}=o h_{i} \quad \forall i \in I \tag{4.26}
\end{equation*}
$$

Products in inventory can be consumed in the domestic market or exported. However, they must be exactly consumed (equation 4.26).

$$
\begin{equation*}
{i m p x_{i}+i m p y_{i}=\text { import }_{i} \quad \forall i \in I, ~}_{\text {in }} \tag{4.27}
\end{equation*}
$$

Imported products can be consumed in the domestic market or exported. The amount of import a product is as needed (equation 4.27).

$$
\begin{equation*}
\sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right)=T_{i} \quad \forall i \in I \tag{4.28}
\end{equation*}
$$

Each area has a measured productivity for each product. So, the sum product of productivity and amount of area is equal to total amount of production (equation 4.28).

$$
\begin{align*}
\sum_{\forall i \in I} k a_{i j} & \leq K_{j}-b_{\text {FallowArea }, j} & \forall j \in J \\
\sum_{i \in m=\text { Cereals }} k a_{i j} & \leq b_{\text {Cereals }, j} & \forall j \in J  \tag{4.29}\\
\sum_{i \in m=\text { Vegetables }} k a_{i j} & \leq b_{\text {Vegetables }, j} & \forall j \in J \\
\sum_{i \in m=F r u i t s} k a_{i j} & \leq b_{\text {Fruits }, j} & \forall j \in J \\
\sum_{i \in m=\text { OrnamentPlants }} k a_{i j} & \leq b_{\text {OrnamentPlants }, j} & \forall j \in J
\end{align*}
$$

The amount of fertile lands of each area was measured and these areas are separated according to the plantation of product groups. The sum of used area for production of all products can not to be higher than the amount of fertile lands in a region and followed areas cannot be used. Moreover, there are upper bounds of land which can be used for the production of all product groups for each region (equation 4.29).

$$
\begin{equation*}
x_{i}, y_{i}, k a_{i j}, \text { import }_{i}, i m p x_{i}, i m p y_{i}, \text { oh } x_{i}, \text { ohy } y_{i} \geq 0 \quad \forall i \in I, \forall j \in J \tag{4.30}
\end{equation*}
$$

All variables must be positive (equation 4.30).

### 4.3 Model 3: LP Approach 3

The second model can reflect a real life well but there is another handicap occurred. Uncultivated lands or fallowed areas caused a big economic problem (More details will be given following parts). Fallowed areas occur when a rest necessity of some parts of cultivated lands. In other words, when the same product is cultivated on a land to consecutive years, its yield can reduce. On the other hand, some other products can be cultivated on this land next year. The third model defines the products that can be cultivated in this land next year according to their yields. Thus fallowed areas were used in the third model.

### 4.3.1 Sets of model 3:

$I$ : set of products.
$J$ : set of regions be appropriate for agricultural production.

M: set of product groups.

### 4.3.2 Parameters of model 3:

$p_{i}$ : Unit domestic price of product i (\$/ton)
$e_{i}$ : Unit export price of product i (\$/ton)
$d_{i}$ : Domestic demand of product i for the specific year (ton)
$o_{i}$ : Export demand of product i for the specific year (ton)
$c_{i}$ : Unit cost of unsold product i $(\$ /$ ton $)$
$K_{j}$ : Amount of fertile land in region j (decare)
$r_{j}$ : Opportunity cost of unused fertile agricultural area in region j (\$/decare)
$\operatorname{cost}_{i j}$ : Unit cost of planting product i in region j ( $\$ /$ decare)
$v_{i j}$ : Productivity level of product i in region j (ton/decare)
imp $_{\text {Cost }}^{i}$ : Unit cost of imported product i $(\$ /$ ton $)$
$o h_{i}$ : On hand inventory of product i (ton)
$b_{m j}$ : Usable amount of area j to produce product group m

### 4.3.3 Decision variables of model 3:

$x_{i}$ : Amount of production of product i for domestic consumption for the specific year (ton)
$y_{i}$ : Amount of production to export of product i for the specific year (ton) $k a_{i j}$ : Amount of needed area in region j to produce product i (decare)
$T_{i}$ : Total amount of production of product i for the specific year (ton)
import $_{i}$ : Amount of import of product $i$ for the specific year (ton)
impx $_{i}$ : Amount of imported product i which is consumed in domestic market (ton)
impy $_{i}$ : Amount of imported product i which for export (ton)
ohx $x_{i}$ : Amount of on-hand inventory product i which is consumed in domestic market (ton)
ohy $y_{i}$ : Amount of on-hand inventory of product i to export (ton)

### 4.3.4 Model 3:

$$
\begin{align*}
& \max _{\text {profit }} \sum_{\text {צieI }}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \\
& +\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+\text { ohy }_{i}\right)\right) \\
& -\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \\
& -\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \\
& -\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \\
& -\sum_{\text {VieI }}\left(\text { imp } \text { Cost }_{i} * \text { import }_{i}\right) \\
& \text { s.t. } \\
& x_{i}+y_{i} \leq T_{i} \\
& x_{i}+i m p x_{i}+o h x_{i}=d_{i} \\
& y_{i}+i m p y_{i}+o h y_{i} \leq o_{i} \\
& o h x_{i}+o h y_{i}=o h_{i} \\
& \text { impx }_{i}+\text { impy }_{i}=\text { import }_{i} \\
& \sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right)=T_{i} \\
& \sum_{\forall i \in I} k a_{i j} \leq K_{j} \\
& \begin{array}{c}
\sum_{i \in m=\text { Cereals }} k a_{i j} \leq b_{\text {Cereals }, j}+b_{\text {FallowArea }, j} \\
\sum_{i \in m=\text { Vegetables }} k a_{i j} \leq b_{\text {Vegetables }, j}+b_{\text {FallowArea }, j}
\end{array} \\
& \sum_{i \in m=\text { Fruits }} k a_{i j} \leq b_{\text {Fruits }, j}+b_{\text {FallowArea }, j} \\
& \sum_{i \in m=\text { OrnamentPlants }} k a_{i j} \leq b_{\text {OrnamentPlants }, j}+b_{\text {FallowArea, } j} \quad \forall j \in J \\
& i \in m=\text { OrnamentPlants } \\
& x_{i}, y_{i} \geq 0 \\
& \forall i \in I \\
& \text { import }_{i}, \text { impx }_{i}, \text { impy }_{i} \geq 0 \\
& \text { oh } x_{i}, \text { ohy }_{i} \geq 0 \\
& k a_{i j} \geq 0  \tag{4.31}\\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I \\
& \forall j \in J \\
& \forall j \in J \\
& \forall j \in J \\
& \forall j \in J \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I, \forall j \in J
\end{align*}
$$

### 4.3.5 Description of model 3:

### 4.3.5.1 Objective function of model 3:

The revenue according to domestic consumption:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \tag{4.32}
\end{equation*}
$$

The domestic market demand is satisfied by the sum of domestic production, import and on hand inventory usage for domestic consumption. The sum of the product of price and the domestic consumption gives us the revenue.

The revenue of export:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \tag{4.33}
\end{equation*}
$$

Overseas demand is satisfied likewise domestic market demand.

Unsold cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \tag{4.34}
\end{equation*}
$$

For a product, if the sum of production for domestic consumption and production for export is not equal to (lower than) total production, there are the unconsumed amount of that product. Additionally, unsold cost of a product is defined as a parameter according to these unconsumed products. If a product is perishable like tabooli, its unsold cost is equal production cost; otherwise, (like wheat) unsold cost is equal holding cost.

Production cost:

$$
\begin{equation*}
\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \tag{4.35}
\end{equation*}
$$

There is a unit production cost to produce a product on a region and a decision variable which is the amount of land used to produce a product. The sum product of this two gives total production cost.

Opportunity cost:

$$
\begin{equation*}
\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \tag{4.36}
\end{equation*}
$$

The unused fertile lands cause economic loss. In other words, some products can be planted on uncropped lands and earned income. So, the unit opportunity cost was determined for each region as the average price of all appropriate products which can be planted a region. The sum product of uncropped area and unit opportunity cost gives total opportunity cost.

Import Cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(\text { imp Cost }_{i} * \text { import }_{i}\right) \tag{4.37}
\end{equation*}
$$

The sum product of unit import cost and amount of import of each item gives total import cost.

### 4.3.5.2 Constraints of model 3:

$$
\begin{equation*}
x_{i}+y_{i} \leq T_{i} \quad \forall i \in I \tag{4.38}
\end{equation*}
$$

The sum of domestic and export sales of a product which was produced domestically must be lower than the total amount of domestic production (equation 4.38).

$$
\begin{equation*}
x_{i}+i m p x_{i}+o h x_{i}=d_{i} \quad \forall i \in I \tag{4.39}
\end{equation*}
$$

There are three ways to satisfy the domestic demand as follows, domestic production, import, and stocks. Domestic demand has to be satisfied (equation 4.39).

$$
\begin{equation*}
y_{i}+i m p y_{i}+o h y_{i} \leq o_{i} \quad \forall i \in I \tag{4.40}
\end{equation*}
$$

Likewise domestic demand, there are also three ways to satisfy the overseas demand. Note that, the imported products can be exported. Overseas demand has not to be satisfied completely (equation 4.40).

$$
\begin{equation*}
o h x_{i}+o h y_{i}=o h_{i} \quad \forall i \in I \tag{4.41}
\end{equation*}
$$

Products in inventory can be consumed in the domestic market or exported. However, they must be exactly consumed (equation 4.41).

$$
\begin{equation*}
{i m p x_{i}+i m p y_{i}=\text { import }_{i} \quad \forall i \in I, ~}_{\text {in }} \tag{4.42}
\end{equation*}
$$

Imported products can be consumed in the domestic market or exported. The amount of import a product is as needed (equation 4.42).

$$
\begin{equation*}
\sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right)=T_{i} \quad \forall i \in I \tag{4.43}
\end{equation*}
$$

Each area has a measured productivity for each product. So, the sum product of productivity and amount of area is equal to total amount of production (equation 4.43).

$$
\begin{array}{rlrl}
\sum_{\forall i \in I} k a_{i j} & \leq K_{j} & \forall j \in J \\
\sum_{i \in m=\text { Cereals }} k a_{i j} & \leq b_{\text {Cereals }, j}+b_{\text {FallowArea }, j} & \forall j \in J  \tag{4.44}\\
\sum_{i \in m=\text { Vegetables }} k a_{i j} \leq b_{\text {Vegetables }, j}+b_{\text {FallowArea }, j} & \forall j \in J \\
\sum_{i \in m=\text { Fruits }}^{i \in m} k a_{i j} & \leq b_{\text {Fruits }, j}+b_{\text {FallowArea, } j} & \forall j \in J \\
\sum_{i \in m=\text { OrnamentPlants }} k a_{i j} & \leq b_{\text {OrnamentPlants }, j}+b_{\text {FallowArea, } j} & \forall j \in J
\end{array}
$$

The amount of fertile lands of each area was measured also these areas are separated according to the plantation of product groups. The sum of used area for production of all products can not to be higher than the amount of fertile lands in a region. Moreover, there are upper bounds of land which can be used for the production of all product groups for each region. When it is necessary, fallowed areas can be used for the production of any product in each region. The yields of products are determinative for usages of fallowed areas (equation 4.44).

$$
\begin{equation*}
x_{i}, y_{i}, k a_{i j}, \text { import }_{i}, i m p x_{i}, \text { impy }_{i}, \text { oh }_{i}, \text { oh }_{i} \geq 0 \quad \forall i \in I, \forall j \in J \tag{4.45}
\end{equation*}
$$

All variables must be positive (equation 4.45).

### 4.4 Model 4: LP Approach 4

An additional constraint was added in the fourth model to protect fruit orchards. Previously designed models it was possible to crop products which were used to crop by other product groups on fruit orchards instead of fruits. So lower bounds of fruit orchards areas were added.

### 4.4.1 Sets of model 4:

$I$ : set of products.
$J$ : set of regions be appropriate for agricultural production.
$M$ : set of product groups.

### 4.4.2 Parameters of model 4:

$p_{i}$ : Unit domestic price of product i (\$/ton)
$e_{i}$ : Unit export price of product i (\$/ton)
$d_{i}$ : Domestic demand of product i for the specific year (ton)
$o_{i}$ : Export demand of product i for the specific year (ton)
$c_{i}$ : Unit cost of unsold product i $(\$ /$ ton $)$
$K_{j}$ : Amount of fertile land in region j (decare)
$r_{j}$ : Opportunity cost of unused fertile agricultural area in region j ( $\$ /$ decare)
$\operatorname{cost}_{i j}$ : Unit cost of planting product i in region j ( $\$ /$ decare)
$v_{i j}$ : Productivity level of product i in region j (ton/decare)
impCost $_{i}$ : Unit cost of imported product i (\$/ton)
$o h_{i}$ : On hand inventory of product i (ton)
$b_{m j}$ : Usable amount of area j to produce product group m
$L B_{i j}$ : Lower bound of area in region j to produce product i

### 4.4.3 Decision variables of model 4:

$x_{i}$ : Amount of production of product i for domestic consumption for the specific year (ton)
$y_{i}$ : Amount of production to export of product i for the specific year (ton)
$k a_{i j}$ : Amount of needed area in region j to produce product i (decare)
$T_{i}$ : Total amount of production of product i for the specific year (ton)
import $_{i}$ : Amount of import of product i for the specific year (ton)
$\operatorname{impx} x_{i}$ : Amount of imported product i which is consumed in domestic market (ton)
impy $_{i}$ : Amount of imported product i which for export (ton)
ohx $x_{i}$ : Amount of on-hand inventory product i which is consumed in domestic market (ton)
ohy $y_{i}$ : Amount of on-hand inventory of product i to export (ton)

### 4.4.4 Model 4:

$$
\begin{align*}
& \max _{\text {profit }} \sum_{\text {צieI }}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \\

& \forall i \in I, \forall j \in J \\
& \forall j \in J \\
& \forall j \in J \\
& \forall j \in J \\
& \forall j \in J \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I \\
& \forall i \in I, \forall j \in J
\end{align*}
$$

### 4.4.5 Description of model 4:

### 4.4.5.1 Objective function of model 4:

The revenue according to domestic consumption:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(p_{i} *\left(x_{i}+i m p x_{i}+o h x_{i}\right)\right) \tag{4.47}
\end{equation*}
$$

The domestic market demand is satisfied by the sum of domestic production, import and on hand inventory usage for domestic consumption. The sum of the product of price and the domestic consumption gives us the revenue.

The revenue of export:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(e_{i} *\left(y_{i}+i m p y_{i}+o h y_{i}\right)\right) \tag{4.48}
\end{equation*}
$$

Overseas demand is satisfied likewise domestic market demand.

Unsold cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left[c_{i} *\left(T_{i}-x_{i}-y_{i}\right)\right] \tag{4.49}
\end{equation*}
$$

For a product, if the sum of production for domestic consumption and production for export is not equal to (lower than) total production, there are unconsumed amount of that product. Additionally, unsold cost of a product is defined as a parameter according to these unconsumed products. If a product is perishable like lettuce, its unsold cost is equal production cost; otherwise, (like wheat) unsold cost is equal holding cost.

Production cost:

$$
\begin{equation*}
\sum_{\forall i \in I} \sum_{\forall j \in J}\left(\operatorname{cost}_{i j} * k a_{i j}\right) \tag{4.50}
\end{equation*}
$$

There is a unit production cost to produce a product on a region and a decision variable which is the amount of land used to produce a product. The sum product of this two gives total production cost.

Opportunity cost:

$$
\begin{equation*}
\sum_{\forall j \in J}\left[r_{j} *\left(K_{j}-\sum_{\forall i \in I} k a_{i j}\right)\right] \tag{4.51}
\end{equation*}
$$

The unused fertile lands cause economic loss. On the other hand, some products can be planted on uncropped lands and earned income. So, the unit opportunity cost was determined for each region as the average price of all appropriate products which can be planted on that region. The sum product of uncropped area and unit opportunity cost gives total opportunity cost.

Import Cost:

$$
\begin{equation*}
\sum_{\forall i \in I}\left(\text { imp }^{\text {Cost }} i * * \text { import }_{i}\right) \tag{4.52}
\end{equation*}
$$

The sum product of unit import cost and amount of import of each item gives total import cost.

### 4.4.5.2 Constraints of model 4:

$$
\begin{equation*}
x_{i}+y_{i} \leq T_{i} \quad \forall i \in I \tag{4.53}
\end{equation*}
$$

The sum of domestic and export sales of a product which was produced domestically must be lower than the total amount of domestic production (equation 4.53).

$$
\begin{equation*}
x_{i}+i m p x_{i}+o h x_{i}=d_{i} \quad \forall i \in I \tag{4.54}
\end{equation*}
$$

There are three ways to satisfy the domestic demand as follows, domestic production, import, and stocks. Domestic demand has to be satisfied (equation 4.54).

$$
\begin{equation*}
y_{i}+i m p y_{i}+o h y_{i} \leq o_{i} \quad \forall i \in I \tag{4.55}
\end{equation*}
$$

Likewise domestic demand, there are also three ways to satisfy the overseas demand. Note that, the imported products can be exported. Overseas demand has not to be satisfied completely (equation 4.55).

$$
\begin{equation*}
o h x_{i}+o h y_{i}=o h_{i} \quad \forall i \in I \tag{4.56}
\end{equation*}
$$

Products in inventory can be consumed in the domestic market or exported. However, they must be exactly consumed (equation 4.56).

$$
\begin{equation*}
{i m p x_{i}+i m p y_{i}=\text { import }_{i} \quad \forall i \in I, ~}_{\text {in }} \tag{4.57}
\end{equation*}
$$

Imported products can be consumed in the domestic market or exported. The amount of import a product is as needed (equation 4.57).

$$
\begin{equation*}
\sum_{\forall j \in J}\left(v_{i j} * k a_{i j}\right)=T_{i} \quad \forall i \in I \tag{4.58}
\end{equation*}
$$

Each area has a measured productivity for each product. So, the sum product of productivity and amount of area is equal to total amount of production (equation 4.58).

$$
\begin{array}{rlrl}
\sum_{\forall i \in I} k a_{i j} & \leq K_{j} & \forall j \in J \\
k a_{i j} & \geq L B_{i j} & & \forall i \in I, \forall j \in J \\
\sum_{i \in m=\text { Cereals }} k a_{i j} & \leq b_{\text {Cereals }, j}+b_{\text {FallowArea, } j} & \forall j \in J \\
\sum_{i \in m=\text { Vegetables }} k a_{i j} & \leq b_{\text {Vegetables }, j}+b_{\text {FallowArea }, j} & \forall j \in J \\
\sum_{i \in m=F r u i t s} k a_{i j} & \leq b_{\text {Fruits }, j}+b_{\text {FallowArea }, j} & \forall j \in J \\
\sum_{i \in m=\text { OrnamentPlants }} k a_{i j} & \leq b_{\text {OrnamentPlants }, j}+b_{\text {FallowArea }, j} & \forall j \in J
\end{array}
$$

The amount of fertile lands of each area was measured also these areas are separated according to the plantation of product groups. The sum of used area for production of all products can not to be higher than the amount of fertile lands in a region. Moreover, there are upper bounds of land which can be used for the production of all product groups for each region. When it is necessary, fallowed areas can be used for the production of any product in each region. The values of products' yields are determinative to be used fallowed area. Furthermore, area lower bounds can be specified for production of any product in a region. This constraint was created for especially products grew on a tree (equation 4.59).

$$
\begin{equation*}
x_{i}, y_{i}, k a_{i j}, \text { import }_{i}, \text { imp }_{i}, \text { impy }_{i}, \text { oh } x_{i}, \text { ohy } y_{i} \geq 0 \quad \forall i \in I, \forall j \in J \tag{4.60}
\end{equation*}
$$

All variables must be positive (equation 4.60).

### 4.5 The Comparison of the Models

To optimize agricultural lands of Turkey, 4 LP models were designed. Even if, each model resemble with each other, their features and outputs differ. These differences are shown Table (4.1)

| - | Criterias | model1 | model2 | model3 | model4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| features | 1. Lower bounds of areas for individual products | - | - | - | $\checkmark$ |
|  | 2. Upper bounds of areas for product groups | - | $\checkmark$ | $\checkmark$ | $\checkmark$ |
|  | 3. Usage of fallowed areas | $\checkmark$ | - | $\checkmark$ | $\checkmark$ |
|  | 4. Exact satisfaction of domestic demand | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
|  | 5. Exact satisfaction of export demand | - | - | - | - |
|  | 6. Tendency of production instead of import | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
|  | 7. The highest applicability | - | - | - | $\checkmark$ |
| outputs | 8. Maximum import | - | $\checkmark$ | - | - |
|  | 9. Minimum import | $\checkmark$ | - | - | - |
|  | 10. Maximum export | $\checkmark$ | - | - | - |
|  | 11. Minimum export | - | $\checkmark$ | - | - |
|  | 12. Maximum profit | $\checkmark$ | - | - | - |
|  | 13. Minimum profit | - | $\checkmark$ | - | - |

Table 4.1: The differences of the models.

All of the models can be applied to different conditions. For example, model 1 must be applied on a country or region which had very few agricultural activities before because model 1 has few area constraints and it defines regional area usages to produce products more freely (detailed information were given in previous sections). Model 2 gives solution, if fallowed areas does not need to be used in a country. Model 3 reorganize usage of fallowed areas. As for model 4 works highly based on existing agricultural system of a country. So, model 4 is more favorable for Turkey.

## Chapter 5

## Data Collection

Turkey has a big potential of product variety in the field of agriculture. Since designed optimization models work on all regions of Turkey, all products which can be grown were tried to include in all models. Consequently, 136 base products were chosen and it is considered that these products reflect product variety with a high degree. Moreover, these products were classified under 4 product groups. The list of base products and product groups is shown in Table (5.1)

As mentioned in a previous chapter, there are 12 agricultural regions in Turkey according to TURKSTAT. These regions were used in models likewise.

One of the basic aim of each of the model is to maximize the agricultural profitability related to the total production at an agricultural year. The model needs real-like estimated parameters to be successful. Moreover, the parameters estimation of incipient season is toilsome, time-consuming and multidisciplinary job. To check applicability of the models and to gain time, real data of 2013 was used as parameters of models. Some establishments and their web sites were helpful to obtain data. TURKSTAT, FAO, TARSIM are some of them.

In addition, parameter of opportunity cost of uncropped lands (opportunity cost of unused lands explained in previous parts.) was calculated as follows:

| Cereals | Vegetables | Fruits | OrnamentPlants |
| :---: | :---: | :---: | :---: |
| wheat | scallion | grape | indorornamentalplants |
| corn | onion | banana | bulb |
| riceplant | garlic | kiwi | ornamentalplants |
| barley | driedgarlic | avocado |  |
| rye | leek | Fig |  |
| oat | carrot | orange |  |
| millet | swede | mandarin |  |
| carnarygrass | redbeet | lemon |  |
| tricale | celery | grapefruit |  |
| sorghum | turnip | bergamot |  |
| potato | radish | apple |  |
| broadbean | tomato | pear |  |
| chickpea | cucumber | quince |  |
| horicot | gherkin | loquat |  |
| redlentil | pepper | medlar |  |
| greenlentil | okra | nectarine |  |
| vetch | eggplant | peach |  |
| greekclover | zucchini | plum |  |
| chickling | pumpkin | apricot |  |
| jeurselamartichoke | pease | wildapricot |  |
| soya | bean | cherry |  |
| peanut | pea | morello |  |
| sunflover | favabean | cranberry |  |
| sesame | cranberrybean | oleaster |  |
| safflover | melon | jujube |  |
| cole | watermelon | strawberry |  |
| cotton | Pepino | raspberry |  |
| hemp | cauli | blackberry |  |
| hash | broccoli | berry |  |
| nicotina | cabbage | pomegranate |  |
| whitebeet | lettuce | persimmon |  |
| viciasativa | artichoke | carob |  |
| clover | spinach | bilberry |  |
| sainfoinseed | gardenoarch | table olive |  |
| fodderbeet | purslane | olive |  |
| sage | tabooli | almond |  |
| lavender | rocket | nut |  |
| melissa | watercress | walnut |  |
| stinger | mint | chestnut |  |
| rose | dill | pistachio |  |
| lupine | asparagus | Tea |  |
| hop | mushroom | chili |  |
|  |  | aniseed |  |
|  |  | cumin |  |
|  |  | raziyane |  |
|  |  | coriander |  |
|  |  | nigella |  |
|  |  | thyme |  |
|  |  | ling |  |

Table 5.1: List of base products and product groups.

Opportunity Cost of Uncropped Land in a Region(\$/decare) = average[Unit Price of product that can be cropped in related region $(\$ /$ ton $)$

* Productivity(ton/decare)]

On hand inventories of all products were taken to be zero because not enough information is available about inventory levels in stocks.

The models outputs may give some results such that the production is more than the consumption in that case production surplus of some products may occur. There are three types of cost of production surplus according to product types. These types are shown as follows:

- Cost of perishable products: average unit production cost of products
- Holding cost: unit cost of products which hold in cold room
- No cost: these products have long shelf life

The unit import prices of products in 2013 were used in models as unit import costs, but prices of some products could not be obtained, so big numbers were taken as unit import costs of such products, so that the models do not import these products.

The upper bounds of product groups' areas and fallowed areas were determined according to cultivated areas in 2013.

Some values in some parameters could not be found, so these values were estimated, if possible.

## Chapter 6

## Data Analysis and Results

### 6.1 Models Solving and DSS (Decision Support System)

The models were solved by a mathematical problem solver program called GAMS. Although data can be written in this program, it is not quite easy to write large amount of data in it. So, we used excel to load data into gams. Moreover, a DSS based on excel vba was designed to make these jobs easy. Thanks to DSS, sets and parameters sheets are formed automatically. DSS also enables to run model and to reach results easily. In other words, users do not need to labor with engineering jobs, it is enough that they press buttons and fill parameter tables. The figure (6.1) shows user interface of DSS:

Figure 6.1: Figure of DSS interface.

### 6.2 Results

Same data was used for each model and detailed information about data was given in previous chapter. Each model was run and outcomes were obtained successfully. As expected, some outcomes of models were different and some of them is the same. These outcomes will examined in detail in this section.

### 6.2.1 Production

The purposes of the models are increasing agricultural profit based on production. So amounts of total productions of some important products (also see Appendix
A. 1 for production levels for all products) will be examined in detail. Table of this outcome is shown below (Table (6.1) )

|  | Model 1 | Model 2 | Model 3 | Model 4 |

TABLE 6.1: Amount of production of some products for each model (ton).

As is seen from Table (6.1), production amounts of lots of the products are same for each model. Hereinbefore, all models have same base structure but they separated with additional constraints. So, many of products were produced as much as demands in all models. On the other hand, some production levels in model 4 are bigger compared to the other models'. The reason for this is area lower bounds constraint in model 4. Thanks to defined area lower bound of some product, productions of these products exceeded their demands. Likewise, model 2 gave

Figure 6.2: The comparison of model and real productions (ton).
lower production levels of some products than the others. Fallowed areas were not used in this model and remaining available lands were not sufficient. Graphical display of models and real production levels comparison for some products are shown Figure (6.2):

Turkey has a big population and big amount of produced product are spent for consumption. Table (6.2) shows consumptions amounts of some most produced products (also see Appendix A. 2 for all products). Since demands were constant, amounts of consumptions were same for all models except model 2. Production of model 2 could not satisfy demand because of unused fallowed areas. In addition, demands of some products could not be satisfied by domestic production of any model. Because import costs of those products are smaller than production cost of them. So, these products were imported. (This issue was examined in Chapter 7)

TABLE 6.2: Table of production for consumption of some products (ton).

Domestic demands of nearly all of products were satisfied by production of models. For previously explained reasons, demand satisfaction of model 2 was lowest.

However, export demand satisfactions of products by production were lower than domestic demand satisfactions. There are not any exact export demand satisfactions constraints in any models so there are not penalty for unsatisfied export demands. The lowest satisfaction was occurred by model 2 again (You can reach the detailed table of export demand satisfaction by production in Appendix A.3).

We could not reach the correct domestic and export demands of indoor ornamental plants, bulbs and ornamental plants from any data source. So, approximate
values were used for them.

### 6.2.2 Import

In real life, Turkey imports a lot of agricultural product in large quantities. On the other hand, models decrease imports compared to real import levels. Decreasing import amounts show that models work well. Even so, optimization models could not finish import completely because production costs are bigger than import costs for some products (also see Chapter 7 for the examinations of effects of high production costs). Table of products' import amounts is shown below (Table (6.3)):

|  | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| melon | 1660788 | 1660788 | 1660788 | 1660788 |
| cabbage | 713002 | 713002 | 713002 | 713002 |

| horicot | 247016 | 247016 | 247016 | 247016 |
| sunflover | 2598256 | 2598256 | 2598256 | 2598256 |
| carnarygrass |  | 3031 |  |  |
| wheat |  | 10619349 |  |  |
| greenlentil |  | 150121 |  |  |
| millet |  | 15981 |  |  |

Table 6.3: Table of total imports of products (ton).

Models produced same import values for some products due to same reasons with same production levels of some products. In addition, model 2 gave more import than others because model 2 use less fertile lands because of unused fallowed areas.

As mentioned before, imported products is not used for only consumption, they also used for export. If import for export is profitable for any product, models
let to occur this. Table 6.4 indicates total imports and tables of import for consumption and import for export are shown below (Tables (6.4)) and (6.5))):

|  | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| melon | 1655639 | 1655639 | 1655639 | 1655639 |
| cabbage | 709498 | 709498 | 709498 | 709498 |

| millet |  | 75 |  |  |
| greenlentil |  | 98706 |  |  |
| carnarygrass |  | 546 |  |  |

Table 6.5: Table of Import for export (ton).

Most of the imports which models produce were used for consumption and there were trades of goods in small quantities. An imported product which has unit import cost less than unit export price can be exported. In addition, there may be two reason to import products. One of them is less fertile lands and the other

Figure 6.3: Import results of models (ton).
one is high production costs. Reasons of import will be examined in Chapter 7 (also see Section 7.1).

Graphical display of import results of models is shown in Figure 6.3.

The total values of imported product that given by model 1, model 3 and model 4 were approximately 2 billion dollars and model 2 gave approximately 5.5 billion dollars total import value. In fact, Turkey's total agricultural products import value was approximately 13 billion dollars in 2013. It is clear that models decreased total import value of agricultural products.

### 6.2.3 Area Usage

The most important job of the models is to define that how much land in a region that has to be used to plant a product. All of the other outputs which were mentioned previously such as production, export, import depend on this output called area usage.

Firstly, area usage will be examined on Mediterranean Region for all models comparatively. Mediterranean Region is one of the 12 agricultural regions and it has biggest product range. Table (6.6) shows area usages of it.

| MEDITERRANEAN | Model 1 | Model 2 | Model 3 | Model 4 | Real <br> Area <br> Usage |
| :---: | :---: | :---: | :---: | :---: | :---: |
| grape |  | 1,402,898 | 1,614,703 | 700,000 | 789,899 |
| banana | 90,949 | 90,949 | 90,949 | 90,949 | 46,700 |

Table 6.6: Table of area usage of Mediterranean Region (decare).

As is seen from Table (6.6), the models produced different amounts of used areas to produce most of the products. Additionally, amounts of used areas produced by models were generally different from real area usages. But some results of model 4 were close with real area usages. The reason of this, the lower bounds of area usages of some products (especially orchards) in model 4 were taken close to real area usage in 2013.

Area usages tables of models with comparison of real area usages for all regions were added in Appendix B. The interpretation of these tables are similar with area usage table of Mediterranean Region.

Secondly, we will examine area usages on all regions for some products and these products are wheat, tomato, tea, table olive and olive.

| WHEAT | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| Mediterranean | 19.678 .471 | 15.279 .356 | 16.838 .122 | 16.838 .122 |
| Western Anatolia | 32.121 .085 | 20.552 .975 | 32.687 .462 | 32.687 .462 |
| Western Blacksea | 18.568 .157 |  |  |  |
| Western Marmara | 4.261 .492 | 12.544 .868 | 12.942 .044 | 12.942 .044 |
| Eastern Blacksea |  |  |  |  |
| Eastern Marmara |  | 8.400 .281 | 10.990 .355 | 10.990 .355 |
| Aegean | 24.282 .213 | 6.592 .826 | 14.531 .558 | 14.531 .558 |
| Southeastern Anatolia | 4.038 .445 | 23.434 .371 | 25.638 .105 | 25.638 .105 |
| Istanbul |  | 643.418 |  |  |
| Northeastern Anatolia |  | 6.882 .763 | 1.745 .431 | 1.745 .431 |
| Central Anatolia | 36.114 .163 | 2.497 .991 | 19.046 .664 | 19.046 .664 |
| Middleestern Anatolia | 9.535 .559 |  |  |  |
| sum= | 148.599 .587 | 96.828 .850 | 134.419 .740 | 134.419 .740 |

Table 6.7: Table of area usages in all regions to produce wheat(decare)

As is seen from Table (6.7), any model did not offer to produce wheat in Eastern Blacksea Region because of production cost and yield of wheat in this region. Furthermore, model 3 and model 4 gave some area usages results for wheat because both models have same product group upper bounds constraints and lower bound constraints in model 4 are available for only fruits. Model 2 had given significant wheat import due to explained reasons in previous section, so this model used fewest area to produce wheat.

| TABLEOLIVE and <br> OLIVE | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| Mediterranean |  | 1.060 .711 |  | 1.370 .000 |
| Western Anatolia |  | 1.019 .771 | 596.657 | 18.000 |
| Western Blacksea |  |  |  | 384.366 |
| Western Marmara | 2.957 .391 |  |  | 1.509 .385 |
| Eastern Blacksea | 1.221 .602 |  |  | 36.734 |
| Eastern Marmara | 635.948 | 825.738 |  | 540.097 |
| Aegean |  | 7.106 .989 | 7.702 .990 | 4.000 .000 |
| Southeastern Anatolia |  |  | 3.868 .054 | 1.557 .719 |
| Istanbul |  |  |  |  |
| Northeastern Anatolia |  |  |  |  |
| Central Anatolia |  |  |  |  |
| Middleestern Anatolia |  |  |  |  |
| sum= | 4.814 .940 | 10.013 .210 | 12.167 .702 | 9.416 .301 |

Table 6.8: Table of area usages in all regions to produce table olive and olive(decare)

The total area usages for table olive and olive production in all region are shown in Table (6.8). The upper bound areas for table olive and olive in regions were available in model 4, so this model used more number of region to produce this product. Moreover, Istanbul, Northeastern Anatolia, Central Anatolia and Middleestern Anatolia were not used by any models to produce this product because of yields of them in these regions.

| TOMATO | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| Mediterranean |  | 698.923 | 1.542 .054 | 1.589 .651 |
| Western Anatolia |  |  |  |  |
| Western Blacksea |  | 889.468 |  |  |
| Western Marmara |  |  |  |  |
| Eastern Blacksea |  |  |  |  |
| Eastern Marmara | 1.709 .411 |  |  | 36.644 |
| Aegean |  | 271.266 |  |  |
| Southeastern Anatolia |  |  |  |  |
| Istanbul |  |  |  |  |
| Northeastern Anatolia |  |  |  |  |
| Central Anatolia |  |  |  |  |
| Middleestern Anatolia |  | 220.941 | 504.502 | 294.087 |
| sum= | 1.709 .411 | 2.080 .597 | 2.046 .556 | 1.920 .382 |

Table 6.9: Table of area usages in all regions to produce tomato(decare)

As is seen from Table (6.9), model 1 offer to use only Eastern Marmara Region to produce tomato, because this model used areas in regions more freely compared to other models. Moreover other models used areas of limited number of regions to produce this product because of yield and production cost of it in non-offered regions.

| TEA | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| Eastern Blacksea | 653.942 | 653.942 | 653.942 | 764.255 |

Table 6.10: Table of area usages in all regions to produce tea(decare)

Table (6.10) shows that tea can be produce in only Eastern Blacksea Region according to all models and this situation reflects the actual state. Moreover, model 4 used more area from others to produce tea because of lower bound of tea
areas in this region. Model 1, model 2 and model 3 used area to produce tea as much as demand satisfaction.

Area usages based on regions and area usages based on products were examined. Now, area usages of models for product groups will be examined comparatively.

Figure 6.4: Area usages of models for each region to produce cereals

Central Anatolia was offered mostly by models to produce cereals (Figure 6.4)and Western Anatolia and Southeastern Anatolia followed Central Anatolia. These three regions lands are more appropriate to cereals production than the other regions and yields of cereals in these regions are generally higher compared to other regions. Moreover, models gave some close regional amounts to produce cereals because all of them used same parameters and they have same base structure. On the other hand, they gave some different regional amounts because developer constraints were added incrementally.

Figure 6.5: Area usages of models for each region to produce fruits

The model 1 gave optimal area usages to produced fruits (Figure 6.5) just based on yield parameters and it gave highest net profit. However when constraints of upper bounds of product groups stepped in model 2, model 3 and model 4 and constraints of lower bounds of products stepped in model 4, optimal area usages changed offered by models and also net profits decreased.

| ornamental plants - model 1 |  |
| :---: | :---: |
|  | ornamental plants - model 4 |

Figure 6.6: Area usages of models for each region to produce ornamental plants

There was an extraordinary situation occurred that area usages to produce ornamental plants (Figure 6.6). Model 1, model 3 and model 4 offered nearly same area usages. The reasons of this, ornamental plants can not be cultivated every region (or their yields are very low in some regions) and ornamental plants production based on their demands requires to be a trace of area usage. Since model 2 could not use all of the fertile lands (because of fallowed areas), its area usages to produce ornamental plants were different from others.

Figure 6.7: Area usages of models for each region to produce vegetables

The most profitable model is model 1 but applicabilities of the models increases from model 1 to model 4 and increasing applicability is an effect of development in models. Differences of area usages offered by models to produce vegetables (Figure 6.7) are cause of the applicability development in models.

As mentioned before, import levels, export demand satisfactions and production depend on area usage results of models (All of decision variables and parameters of models depend on with each other but area usages effect these stated decision variables more). So, decreased or disappeared import levels, high incidence of satisfied export demands and organized production show that models plan area usage effectively.

### 6.2.4 Net Profit

The objectives of models is maximizing net agricultural profit as mentioned before. Table (6.11) indicates net profit values of models. Model 1 and Model 3 had given highest net profit value. Model 1 does not has any area constraint which
make models more appropriated for true conditions and also expectedly decrease net profits of models (also see Section 4.1). So, it was an expected situation that Model 1 has highest net profit. On the other hand, Model 3 has area constraints namely upper bounds of product groups of areas (also see Section 4.3) and it had same highst net profit value with Model 1. The reason of this, defined upper bounds of product groups gave sufficient areas that Model 3 works optimal likewise Model 1. In addition, Model 2 gave a significant negative net profit since the fallowed areas were not used (also see Section 4.2). Moreover, each model was created to stimulate production instead of import. So there is an opportunity cost for unused areas. In other words, fallowed areas caused big economical problem for model 2 and imports and import costs increased because of these unused areas. The fallowed areas can be logically used in production as indicated Model 3 and Model 4 (also see Sections 4.3 and 4.4). While usage of fallowed areas is so important, residential settlements on fertile lands must be out of question. The the constraint of area lower bounds of products in Model 4 decreased net profit but it is acceptable.

|  | Net Profit |
| :--- | :--- |
| model $\mathbf{1}$ | $31,917,410,111$ |
| model 2 | $-52,258,550,187$ |
| model 3 | $31,917,410,111$ |
| model 4 | $30,747,902,848$ |

Table 6.11: Net profits of models(dollar).

### 6.3 Sensitivity Analysis

As we mentioned before, models have same base structure and model 4 is the most suitable one for our purpose among them. So we make sensitivity analysis by examining the shadow prices of model 4 variables to find ways of increasing net profit of this model. First of all, we will examine shadow prices of total production. Table (6.12) shows 10 products which have highest shadow prices
of total production. Increasing production of these 10 products by one ton will increase net profit of model 4 by $\$ 39,243$. So, it can be considered to increase production to start from product which has highest shadow price. However, increasing production does not mean that these products can be sold. The demand of these products must also be increased by other means, ex. advertisements. If production is more than demand, production surplus occurs.

| Product | Shadow Prices of Production |
| :--- | :--- |
| pepino | 11,000 |
| indor ornamental plants | 5,354 |
| rocket | 4,484 |
| watercress | 3,630 |
| ornamental plants | 3,555 |
| nicotina | 3,260 |
| walnut | 2,100 |
| jeurselamartichoke | 2,060 |
| almond | 2,000 |
| nigella | 1,800 |

Table 6.12: Shadow prices of total production

Table (6.13) shows ten products which have highest shadow prices of export demand. Export demand enhancing studies can be started to apply from these products, thus net profit can be increased.

| Product | Shadow Prices of Export Demand |
| :--- | :--- |
| pistachio | 12,160 |
| pepper | 10,340 |
| walnut | 9,510 |
| almond | 8,600 |
| nut | 7,000 |
| fig | 3,227 |
| plum | 2,643 |
| apricot | 2,560 |
| nicotina | 2,443 |
| coriander | 2,380 |

Table 6.13: Shadow prices of export demand

Thus if we are able to increase the export demand each of these 10 products by one ton, the profit may increase by $\$ 60863$. So producing and exporting most profitable products, if we can create demand, may lead us to increase our profit more than the one we obtained from model 4.

## Chapter 7

## Scenario Analysis

The results of models under real conditions were examined in Chapter 6. This time, we examined results of models for different scenarios to make beneficial inferences and suggestions.

### 7.1 Scenario 1: Increasing yield by $\mathbf{1 5 \%}$

We increased yields of products for all regions by $15 \%$ as first scenario analysis. Increasing yields by $15 \%$ affected production and net profit positively and also decreased imports as expected. As is seen from Table (7.1) net profit increased $10 \%$ for model $1,7.8 \%$ for model $2,10 \%$ for model 3 and $8.5 \%$ for model 4 when Scenario 1 was applied.

|  | Net Profit Under <br> Real Conditions | Net Profit with In- <br> creasing Yields | Increasing <br> Rate |
| :--- | :--- | :--- | :--- |
| model 1 | $31,917,410,111$ | $35,139,591,975$ | $10 \%$ |
| model 2 | $-51,258,550,187$ | $-47,254,901,873$ | $7.8 \%$ |
| model 3 | $31,917,410,111$ | $35,139,591,975$ | $10 \%$ |
| model 4 | $30,747,902,848$ | $33,360,233,012$ | $8.5 \%$ |

Table 7.1: The comparison of net profits under real conditions versus increasing yields(dollar)

Moreover, import levels of some products decreased (Table (7.2)). When Table (6.3) and Table (7.2) were compared, the decrease could be observed. However, import levels of some products did not change, although yields increased by $15 \%$. This situation is evident because some products are imported because of less fertile lands and some others are imported because of their high production costs. For this reason, it is necessary that production costs has to be decreased. External dependence problems of fertilizer and seeds must be solved and modern agricultural techniques must be used effectively. Natural fertilizer usage should be encouraged in order to have organic food and not to import inorganic fertilizers.

|  | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| cabbage | 713002 | 713002 | 713002 | 713002 |
| artichoke | 37453 | 37453 | 37453 | 37453 |
| wheat | 0 | 3999873 | 0 | 0 |
| millet | 0 | 15981 | 0 | 0 |
| carnarygrass | 0 | 3031 | 0 | 0 |
| horicot | 0 | 247016 | 0 | 0 |
| sunflover | 2598256 | 2598256 | 2598256 | 2598256 |

Table 7.2: Table of total imports of products according to Scenario 1 (ton).

### 7.2 Scenario 2: Running models with real production amounts

Normally, total production amounts of products had been defined as decision variables in the models. We changed this case situation to take total production amounts of models as parameters instead of decision variables and we analyzed this change as a Scenario. We used real production data in 2013 from FAO and TURKSTAT. The basic aim of this scenario analysis is to observe changes on area usages. Table (7.3) shows these changes.

|  | Model 1 | Model 2 | Model 3 | Model 4 | Available <br> Area |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Mediterranean | $23,385,270$ | $18,697,773$ | $20,648,879$ | $23,385,270$ | $23,385,270$ |
| Western Anatolia | $34,500,466$ | $23,892,613$ | $34,500,466$ | $34,214,954$ | $34,500,466$ |
| Western Blacksea | $1,488,764$ | $7,410,123$ | $1,612,259$ | $3,818,766$ | $20,506,420$ |
| Western Marmara | $15,262,906$ | $13,300,542$ | $13,353,077$ | $15,192,561$ | $15,262,906$ |
| Eastern Blacksea | $2,763,318$ | $2,645,772$ | $2,763,814$ | $5,828,745$ | $6,757,423$ |
| Eastern Marmara | $13,111,624$ | $11,891,886$ | $11,364,341$ | $11,509,298$ | $14,501,178$ |
| Aegean | $11,276,797$ | $18,835,714$ | $9,803,833$ | $16,627,117$ | $28,094,540$ |
| Southeastern Anatolia | $31,525,928$ | $23,639,574$ | $25,674,954$ | $31,525,928$ | $31,525,928$ |
| Istanbul | 708,986 | 706,687 | 708,986 | 708,986 | 708,986 |
| Northeastern Anatolia | 356,956 | $4,014,150$ | 233,114 | 491,342 | $12,976,835$ |
| Central Anatolia | $10,207,773$ | $23,017,565$ | $26,738,100$ | $24,875,908$ | $36,864,042$ |
| Middleestern Anatolia | $1,724,764$ | $1,724,764$ | $1,724,764$ | $3,011,034$ | $12,971,127$ |
|  |  |  |  |  |  |
| Sum= | $146,313,552$ | $149,777,163$ | $149,126,588$ | $171,189,909$ | $238,055,121$ |
| Ratio= | $61 \%$ | $63 \%$ | $63 \%$ | $72 \%$ |  |

Table 7.3: Comparison of area usages of models and available areas in 2013 according to Scenario 2(decare).

The data on Available Area column on Table (7.3) reflects the cultivated lands in each region in 2013 and it can be easily observed that the models used between $61 \%$ to $72 \%$ of total real cultivated lands to produce amount of real productions. It can be clearly stated that productions of products can be increased with the help of production area usage reorganization of the models. In addition, all models gave significant negative net profits because of opportunity cost of unused areas.

### 7.3 Scenario 3: Increasing import costs of products 2 times more

We had increased yields in Section 7.1 and imports of some products had decreased but some of them had not changed. The reason of this is unit import costs are lower than unit production costs for some products. We will examine the results this time when import costs of products were increased 2 times more.

|  | Model 1 | Model 2 | Model 3 | Model 4 |
| :--- | :--- | :--- | :--- | :--- |
| wheat |  | $10,625,742$ |  |  |
| millet |  | 15,981 |  |  |
| carnarygrass |  | 3,031 |  |  |
| sunflover |  | $2,598,256$ | $1,861,602$ | $1,861,602$ |

Table 7.4: Table of total imports of products according to Scenario 1 (ton).

The import results of Scenario 3 can be observed from Table (7.4). Unchanged import levels of products (cabbage, artichoke and sunflower) be mentioned in Scenario 1 (Table (7.2)) changed when unit import costs increased. Imports of cabbage and artichoke were set to zero. Furthermore, import level of sunflower also decreased but not to be set to zero. Under Turkey's agricultural conditions, even though fertile lands of Turkey are used effectively by optimization models, import can not be set to zero completely. In addition, production instead of import of some products decreased net profits because of higher production costs:

|  | Net Profit Under Real <br> Conditions | Net Profits according to <br> Scenario 3 |
| :--- | :--- | :--- |
| model 1 | $31,917,410,111$ | $31,311,856$ |
| model 2 | $-51,258,550,187$ | $-56,143,076$ |
| model 3 | $31,917,410,111$ | $30,475,483$ |
| model 4 | $30,747,902,848$ | $29,305,975$ |

Table 7.5: Net profits according to Scenario 3(dollar)

### 7.4 Scenario 4: Increasing and decreasing opportunity costs by $\mathbf{1 5 \%}$

We decreased and increased all opportunity costs of unused areas in regions in this scenario and our basic aim is to observe that changing opportunity costs how to affect net profits of models. As expected, net profits of model 1, model 3 and model 4 did not change because they continued to used all fertile lands in regions
for both case. We had mentioned that reason of significant net profit of model 2 was mostly opportunity costs of unused fertile lands. So, changing opportunity costs by $15 \%$ affected net profit of model 2 as nearly 12 billion dollars. This situation shows big negative economic effect of unused areas.

## Chapter 8

## Conclusion

Agriculture in Turkey has lots of problems. Such as; unused modern techniques, cultivatable land losses, low productivity and yield, high production costs, farmers who give up from production, unorganized production and etc. It is not possible to fix all of these agricultural problems with industrial engineering perspective. So we had do focus towards a problem which we will solve and unorganized production was appropriate for this definition. Unorganized production causes scarcity of some products and/or production surplus of some of the other products every year. This problem could be solved with the help of an optimization model. Thus an optimization model was created and it was improved in time. At the end, there were 4 optimization models which have same base structure and some different additional constraints (for detailed information about models see Chapter 4).

Models were tested with real agricultural data in 2013 and there were no mathematical problem for any of them. Moreover outputs of the models were examined deeply and no contradictions were determined.

Additionally, a user friendly decision supporting system (DSS) based on excel vba was created so that models can be used easily. The most beneficial attribute of DSS is numbers of products, regions and product groups can be increased or decreased practically. So they can be applied to some other countries and some specific regions. As a result, an institution which has decision-making authority such as Republic of Turkey Ministry of Food, Agriculture and Livestock can do
forecast works of prices, demands and yields for next year and then can offer producers without force that how much land in a region that has to be used to plant a product. Moreover, created DSS helps to be done this job quite easily.

The results of models indicated that agricultural production in fertile lands of Turkey did not satisfy domestic demands completely in spite of the optimal usage of the fertile lands. Residential settlements on fertile lands must be stopped. Fallowed areas should be used for production as well. Population increases and we can not let fertile lands losses anymore every year (also see Chapter 2). Another problem is high production costs. Even though there are sufficient fertile lands in Turkey, high production costs cause the producers dispense with production. As a result of problems import of agricultural products increases.

LP models work well but they can be still improved. Instead of constant parameters, stochastic parameters can provide that better outputs be produced. In other words, linear programming can evolve stochastic programming.

### 8.1 Future Works

LP models work well but they can be still improved. Instead of constant parameters, stochastic parameters can provide that better outputs be produced. In other words, linear programming can evolve stochastic programming. Moreover, models work for one single year. Instead of this, multi-period models can be created to increase usefulness.
